INVESTMENT INSIGHT DASHBOARD REPORT

Analysis of Investor Demographics, Product Ratings, Preferences, and Decision Factors

1. Executive Summary

This report presents an analysis of investor demographics, investment product ratings, investment avenue preferences, investment purposes, and factors influencing investment decisions. The analysis is based on a dashboard created in Power BI using responses from 40 investors.

The dashboard shows that there are 25 male investors and 15 female investors, with an average investor age of 27.80 years. Mutual funds have the highest preference among the four investment avenues displayed. Wealth creation is the most prominent investment purpose, while returns are the strongest factor influencing investment choices in the chart.

The report summarizes the patterns displayed in the dashboard and concludes with recommendations for stakeholders based on those findings.

2. Investor Demographics

The dashboard records 40 investors. Of these, 25 are male and 15 are female. Male investors make up 62.5% of the respondents, while female investors make up 37.5%. The average age of the investors is 27.80 years.

Gender	Number of Investors	Percentage
Male	25	62.5%
Female	15	37.5%
Total	40	100%

The sample therefore contains more male than female respondents. The age slicer groups investors into age categories, allowing the dashboard to be filtered to examine differences between age groups.

3. Investment Product Ratings

The dashboard compares ratings for seven investment products: gold, debentures, government bonds, fixed deposits, equity market, mutual funds, and Public Provident Fund (PPF). Based on the displayed chart, gold receives the highest rating, followed closely by debentures. Government bonds are next, while fixed deposits and equity market receive ratings in the middle range. Mutual funds and PPF have the lowest displayed ratings.

The approximate values visible in the chart are: gold 6, debentures about 5.8, government bonds about 4.7, fixed deposits about 3.6, equity market about 3.5, mutual funds about 2.6, and PPF about 2.0. These are visual estimates from the dashboard image and should be confirmed against the underlying data before formal submission.

4. Average Product Rating by Gender

The dashboard compares the average ratings assigned to investment products by male and female investors. The grouped bar chart shows that ratings vary by product and gender, suggesting that the two groups do not rate every investment product in exactly the same way.

Because the individual bars and legend labels are difficult to distinguish precisely in the dashboard image, this report does not assign exact rating values or a definitive product ranking to each gender.

5. Investment Avenue Preference

The investment avenue chart compares mutual funds, equity, fixed deposits, and Public Provident Fund. Mutual funds have the highest displayed preference, at approximately 18 responses. Equity follows at around 10, fixed deposits at around 9, and Public Provident Fund at around 3.

Investment Avenue	Approximate Preference Count
Mutual Funds	18
Equity	10
Fixed Deposits	9
Public Provident Fund	3

The chart indicates that mutual funds are the most preferred avenue among the four shown, while Public Provident Fund has the lowest preference count.

6. Investment Purpose by Gender

The dashboard compares three investment purposes—wealth creation, savings for the future, and returns—between male and female investors. Wealth creation has the highest displayed values for both genders. The male group has a higher displayed value for wealth creation than the female group. Savings for the future ranks below wealth creation, while returns as a separately stated investment purpose has the lowest displayed values.

These patterns suggest that wealth creation is the leading stated investment purpose among the respondents represented in the dashboard.

7. Factors Influencing Investment Choices

The dashboard presents three factors influencing investment choices: returns, risk, and locking period. Returns has the longest bar, with an approximate displayed value of 175. Risk follows at approximately 100, while locking period is much lower, at around 8.

Factor	Approximate Value Shown
Returns	175
Risk	100

Locking Period	8

The chart indicates that returns is the most influential of the three displayed factors, followed by risk. Locking period has a much smaller value in comparison.

9. Recommendations

Based on the findings presented in the dashboard, the following actions are recommended:

1. **Prioritize highly rated products.** Give greater promotional attention to gold and debentures, which have the highest displayed product ratings, while ensuring that information about benefits and risks is balanced and clear.
2. **Focus marketing on mutual funds.** Prioritize mutual funds in customer engagement because they have the highest preference count among the four investment avenues shown. Continue offering equity and fixed deposits, and improve communication about PPF to address its lower preference in this sample.
3. **Align offerings with wealth-creation goals.** Emphasize products and services that support wealth creation, the most prominent investment purpose in the dashboard, while also providing options suited to future savings.
4. **Communicate returns and risk together.** Since returns is the strongest factor shown and risk is second, present potential returns alongside relevant risks and avoid implying that returns are guaranteed.
5. **Address the needs of different investor groups.** Ensure investment information is relevant to both male and female investors and to the age groups represented in the dataset, rather than assuming that all investors have identical preferences.
6. **Use the underlying data to validate figures.** Before making major business decisions, confirm the approximate chart readings against the underlying dataset and use the exact product ratings, preference counts, and group comparisons.

Note: Numerical values described as approximate were read visually from the dashboard image. They should be verified against the Power BI data before the report is submitted or used for decision-making.

. Conclusion

The Investment Insight Dashboard summarizes the characteristics and preferences of 40 investors. The respondents are predominantly male, and their average age is 27.80 years. Gold and debentures receive the strongest displayed product ratings, while mutual funds are the most preferred investment avenue among the four options compared.

Wealth creation is the most prominent investment purpose in the gender comparison, and returns is the strongest factor influencing investment choices in the factors chart. These findings provide a useful overview of the preferences represented in the dataset. Since the analysis covers 40 respondents and some chart values are approximate readings from the image, the findings should be interpreted within that context.
